## Decision Theory

- Rational individual choice is the central underpining of economic theory
- Do people choose rationally? What do we mean by rationally?

## Allais Paradox

Take $\mathrm{Q}=1$ billion dollars US
Decision problem 1:
Q for sure
(or)
$.1 \times 5 Q, .89 \times 1 Q, .01 \times 0 Q$

Decision problem 2:
$.1 \times 5 \mathrm{Q}, .9 \times 0 \mathrm{Q}$
(or)
$.11 \times 1 \mathrm{Q}, .89 \times 0 \mathrm{Q}$

Decision problem 1:
$1 \times 1 \mathrm{Q}$ for sure [most common choice]
(or)
$.1 \times 5 Q, .89 \times 1 Q, .01 \times 0 Q$

Decision problem 2:
$.1 \times 5 \mathrm{Q}, .9 \times 0 \mathrm{Lmost}$ common choice]
(or)
$.11 \times 1 Q, .89 \times 0 Q$
So $u(1)>.1 u(5)+.89 u(1)+.01 u(0)$ or $u(5)<1.1 u(1)-.1 u(0)$
And $.1 u(5)+.9 u(0)>.11 u(1)+.89 u(0)$ or $u(5)>1.1 u(1)-.1 u(0)$

Notice that the original problem had $Q$ equal to 1 million US. This doesn't work well anymore because most people make the second choice in the first problem and the first choice in the second problem, which is consistent with expected utility

## Risk Preferences: Prospect Theory to the Rescue?

Prospect theory: two differences with expected utility theory

- probability distortion: people tend to exaggerate low probabilities
- reference point: people are not concerned with overall well-being but gains and losses relative to a reference point
the reference point is vague: treated as an unknown value changing from setting to setting in an unexplained manner a bug that renders the theory unusable for economists

## Probability Weighting

Bruhin, Fehr-Duda, and Epper [2007] (economists) estimate probability weighting function in the laboratory
$p_{i}$ is the chance of winning one of two prizes $x_{i} \geq 0$ where $i=1,2$ they conclude that the single largest group of people use a utility function

$$
U=\sum_{i} \frac{.846 p_{i}^{.414}}{.846 p_{i}{ }^{414}+\left(1-p_{i}\right)^{.414}} x_{i}^{1.056}
$$

Note non-linearity in probabilities

## What Else Does This Theory Predict?

A. $\$ 5,000$ for sure (or)
B. a 50-50 coin-flip between $\$ 9,700$ dollars and nothing

- People in the large group using the utility function above should pick B
- Predicts no Allais paradox

## Loss Domain

one of the main hypotheses in prospect theory: risk averse for gains, but risk loving for losses

- hard to present people with the possibility of losses in the laboratory
- initial stake: can change their "reference point"
- consequence: experiments with gains typically for larger stakes than losses
- most of the losses hypothetical rather than real
- maybe people are risk loving for small (real) stakes and risk averse for (real) large stakes?

## Bosch-Domenech and Silvestre 2006

Clever design:

- endowed subjects with money in one experiment
- conducted the gambles in a second experiment several months later
- what they found: risk aversion and risk loving are driven by stakes and not by losses and gains.

## Risk Loving for Losses in the Field

in the recent crisis (and historically) bankers willing to gamble a small probability of a large loss for a modest increase in the average return
Godlewski 2007 argues that this is predicted by prospect theory

- However: standard expected utility theory predicts bankers should gamble on losses.
- the "hail Mary pass" in football: if you are behind gamble, only winning counts, not how much you lose by
- bankers face similar situation: if they win they keep the money; if they lose the government bails them out

## The Problem of Scientific Fraud

- Underpowered or wrong tests
- versus outright fraud
- from Forbes

Ariely published in 2012 what became a highly influential paper in the Proceedings of the National Academy of Sciences called "Signing at the Beginning Makes Ethics Salient and Decreases Dishonest SelfReports in Comparison to Signing at the End."...
worked with an unnamed "insurance company in the southeastern United States," which was willing to give half of a group of their customers a sign-at-the-top honesty pledge form for reporting their current mileage, and the other half their traditional sign-at-the-bottom form. The difference in miles reported was $2,427.8$, or $10.25 \%$ more for the top pledge form, suggesting greater honesty since more miles meant a higher insurance premium

## The Fraud

post on the blog Data Colada, by Uri Simonsohn, Leif Nelson and Joe Simmons... found massive irregularities. These were not subtle problems either, but blatant ones. The end result was not only that the data was not correct, but that it was statistically impossible...

The properties of the Excel file apparently showed that Ariely was the one who created the file and also the one who changed it last...
So it looks like there are two main suspects for the source of the fraud: the insurance company and Dan Ariely...
questions could be raised about why an insurance company would find it desirable to manufacture false data. Not only that, but why would it fabricate the data in a way that helps out the researcher's hypothesis, yet does such a clearly bad job that it is flat out statistically impossible? In addition, according to an article in Science, concerns are starting to be raised about some of Ariely's other work.

## Subjective Uncertainty and the Ellsburg Paradox

## Ellsberg [1961]

Two urns: each contains red balls and black balls
Urn 1: 100 balls, how many red or black is unknown
Urn 2: 50 red and 50 black

Choice 1: bet on urn 1 red or urn 2 red
Choice 2: bet on urn 1 black or urn 2 black

Urn 1: 100 balls, how many red or black is unknown Urn 2: 50 red and 50 black

Choice 1: bet on urn 1 red or urn 2 red [urn 2]
Choice 2: bet on urn 1 black or urn 2 black [urn 2]

1 says that urn 2 red more likely than urn 1 red
2 says that urn 2 black more likely than urn 2 black but this is inconsistent with probabilities that add up to 1

## Ambiguity

Can introduce theory of "ambiguity aversion" as in Schmeidler [1989],
Ghirardato and Marinacci [2000]

- Basically probabilities do not add up to one; remaining probability is assigned to "nature" moving after you make a choice and choosing the worst possibility for you. [The stock market always tumbles right after I buy stocks.]
- Note: non-economists talk about risk versus uncertainty - no model from psychology, only mainstream economists have models about this
- Distinction between risk and uncertainty is due to the economist Frank Knight - in 1921

## Ellsburg Paradox Paradox

we should be able to break the indifference
Urn 1: 1000 balls, how many red or black is unknown
Urn 2: 501 red and 499 black

Choice 1: bet on urn 1 red or urn 2 black [urn 2]
Choice 2: bet on urn 1 black or urn 2 black [urn 2]

Combine this into a single choice:
Bet on urn 1 red, urn 1 black or urn 2 black
Ambiguity aversion says go with urn 2 black...

## Not such a great idea...

But this is a bad idea: flip a coin to decide between urn 1 red and urn 1 black

## Risk Aversion in the Laboratory

In laboratory experiments we often observe what appears to be risk averse behavior over small amount of money (typical payment rates are less than \$50/hour, and play rarely lasts two hours)

How can people be risk averse over gambles involving such an insignificant fraction of wealth?

Rabin [2000]: Risk aversion in the small leads to impossible results in the large
"Suppose we knew a risk-averse person turns down 50-50 lose \$100/gain $\$ 105$ bets for any lifetime wealth level less than $\$ 350,000$, but knew nothing about the degree of her risk aversion for wealth levels above $\$ 350,000$. Then we know that from an initial wealth level of $\$ 340,000$ the person will turn down a 50-50 bet of losing $\$ 4,000$ and gaining \$635,670."

Here we need a reference point

## Present Bias

Fraction of People Making Choice

| Scenario | Choices | Fraction Making Choice |
| :--- | :--- | :--- |
|  | $\$ 175$ now | 0.82 |
|  | $\$ 192$ in 4 weeks | 0.18 |
|  | $\$ 175$ in 26 weeks | 0.37 |
|  | $\$ 192$ in 30 weeks | 0.63 |

Keren and Roelsofsma [1995] (60 observations)

## Quasi-hyperbolic Discounting

$u\left(c_{1}\right)+\theta \sum_{t=2}^{\infty} \delta^{t-1} u\left(c_{t}\right)$
studied by economist Richard Strotz in the mainstream Review of Economic Studies in 1955

Laibson [1997] examines consequences for consumption: in the mainstream Quarterly Journal of Economics - cited 1543 times, so not overlooked by economists

## Uncertain Reward

Hyperbolic/quasi-hyperbolic discounting predicts that present bias should not depend on whether or not the reward is uncertain
fraction Making Choice With Uncertain Reward

| Scenario | Choices | Probability of reward |  |
| :--- | :--- | :--- | :--- |
| Scenario |  | $1.0(60)$ | $0.5(100)$ |
|  | $\$ 175$ now | 0.82 | 0.39 |
|  | $\$ 192$ in 4 weeks | 0.18 | 0.61 |
|  | $\$ 175$ in 26 weeks | 0.37 | 0.33 |
|  | $\$ 192$ in 30 weeks | 0.63 | 0.67 |

## Preference Uncertainty

(based on Villaverde and Mukherji [2003])
Uncertainty about preferences 100 days from now.

- marginal utility of consumption can take on two values 1 or 2 with equal probability
- daily subjective discount factor to a good approximation 1.
- value of todays and tomorrow's marginal utility is know with certainty
- offered 10 today versus 15 tomorrow, you take 10 today with probability 25 .
- preferences 100 days from now are unknown
- ratio of expected utilities is 1 : if you are offered 10 in 100 days versus 14 in 101 days you always take 14

## Commitment?

1) $\$ 175$ in twenty six weeks
2) $\$ 192$ in thirty weeks
3) wait and make the decision twenty six weeks from
single rational decision maker would always prefer flexibility of waiting self-commitment - intentionally limiting our future options - not consistent with standard economic models

- Schelling example: garbage disposal

## Della Vigna and Malemendier 2006 health club memberships

- long-term memberships paid on average $\$ 17$ per visit as against a \$10 per visit fee
- ignore hassle factor of availability of lockers and the need to pay each visit: some evidence that people are trying to make a commitment to attending the health club

## Self-Control Models

2001: Faruk Gul and Wolfgang Pesendorfer; Dekel, Lipman and Rustichini
preferences over menus - lists of which options will be available - with preference for commitment
major topic of ongoing research

- behavioral: postulate rather than a single decision maker each of us has several conflicting selves and that the resolution of internal conflict leads to our final decisions
- pioneered by behaviorists: Shefrin and Thaler in 1981 and Ainslie in 2001
- obvious role in explaining things such as impulsive behavior and drug addiction

## A Note of Caution

Supposed spur of the moment, giving in to temptation and taking immediate gratification at the expense of the future often not
Gambling and sexual behavior

- Eliot Spitzer lost his job as governor of New York because of his "impulsive" behavior in visiting prostitutes
- In fact he paid months in advance (committing himself to seeing prostitutes rather than committing himself to avoiding them)
- once flew a prostitute from Washington D.C. to New York - violating Federal as well as State law
- Rush Limbaugh carrying large quantities of viagra from the Dominican Republic: suspected that he had gone there on a "sex vacation"
- Not done impulsively at the last minute the Las Vegas vacation? planned well in advance

## Procrastination

prominent on Akerlof's list of "behavioral" phenomenon
I quizzed a behavioral economist for examples

- Paying taxes the day before the deadline
- Christmas shopping on Christmas eve
- Buying party supplies for something like a New Years Eve party or a 4th of July party at the last minute
- Buying Halloween costumes at the last minute
- Delaying the purchase of concert tickets
- Waiting to buy plane tickets for Thanksgiving

## Irrationality?

an unpleasant task is delayed until the deadline
if task is unpleasant and we are impatient: the best thing to do is to wait until the deadline

## The Horse and the King

The king had a favorite horse that he loved very much. It was a beautiful and very smart stallion, and the king had taught it all kinds of tricks. The king would ride the horse almost every day, and frequently parade it and show off its tricks to his guards.

A prisoner who was scheduled to be executed soon saw the king with his horse through his cell window and decided to send the king a message. The message said, "Your Royal Highness, if you will spare my life, and let me spend an hour each day with your favorite horse for a year, I will teach your horse to sing."

The king was amused by the offer and granted the request. So, each day the prisoner would be taken from his cell to the horse's paddock, and he would sing to the horse "La-la-la-la" and would feed the horse sugar and carrots and oats, and the horse would neigh. And, all the guards would laugh at him for being so foolish.
One day, one of the guards, who had become somewhat friendly with the prisoner, asked him, "Why do you do such a foolish thing
every day singing to the horse, and letting everyone laugh at you? You know you can't teach a horse to sing. The year will pass, the horse will not sing, and the king will execute you."

The prisoner replied, "A year is a long time. Anything can happen. In a year the king may die. Or I may die. Or the horse may die. Or ...The horse may learn to sing."

## The Health Club Again

evidence that people pay extra to self-commit to exercising
procrastination: delay canceling memberships after stopping attendance
average of 2.3 months before canceling
average amount lost is nearly $\$ 70$
no issue of delaying an unpleasant task until a deadline irrational procrastination?

## Analysis

may take a while after last attending to make the final decision to quit still: why cancel now when we could cancel next month instead? Are people naïve: do not understand that they are procrastinators?
they put off until tomorrow, believing they will act tomorrow, and do not understand that tomorrow they will face the same problem and put off again
maybe some people that behave this way
several kinds of untrue beliefs that might lead to procrastination
in the face of a lifetime of evidence people may falsely believe that they are not procrastinators

## An Alternative from Learning Theory

Della Vigna and Malemendier assert that a canceling a membership is a simple inexpensive procedure: suppose true

- people might falsely believe that it will be a time consuming hassle
- they foolishly they think canceling will involve endless telephone menus, employees who vanish in back rooms for long periods of times and so forth
- are people more likely to be misinformed about something they have observed every day for their entire lives (whether or not they are procrastinators) or something that they have observed infrequently and for which the data indicates costs may be high (canceling)?
- learning theory suggests the latter
